20. ABSTRACT (Continue on reverse side if necessary and identify by block number) Presented in this report are the results of the XM714 delay fuze tests performed by AFATL at Eglin AFB, Florida. The fuze was carried by a lightweight, thin-walled 20mm projectile body with a mechanically locked plastic rotating band. Forty inert fuzes and projectiles were fired to evaluate fuze structural integrity, and 266 live high-explosive (HE) projectiles and fuzes were fired to evaluate fuze performance. Standard M103A1 20mm cases were used with WC870 propellant. The fuzes were fired against aluminum targets of various thicknesses at various impact velocities and impact angles. Fuze delay distances

PREFACE

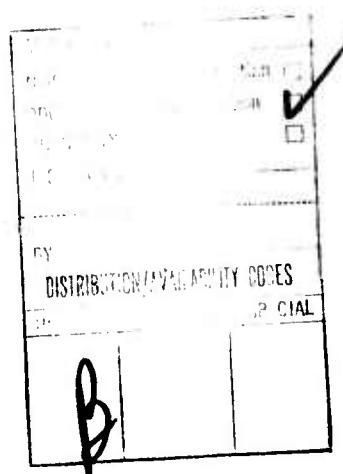

This test was conducted in response to Program Management Directive No. R-P4029(3)/64603F/2079, dated 20 June 1975. Testing began on 7 June 1976. Personnel responsible for testing, evaluation, and report preparation were Mr. Seymour Slotkin, Project Engineer, and 1st Lt William F. Wade, Jr., Test Engineer.

This report has been reviewed and is approved for publication.

SECTION I  
INTRODUCTION

A development program, in support of the Improved 20mm Ammunition Program, was conducted to modify the XM714 fuze for function delay. The modification consisted of replacing the setback spring with a crush washer, removing the self-destruct steel balls, and incorporating a solid ogive. The base thread diameter was increased (larger than the M505 fuze diameter) to permit strengthening the ogive wall for increased fuze survivability during target penetration. This caused an incompatibility with standard 20mm projectiles. A 20mm projectile "fuze tester" compatible with the XM714 delay fuze and M61A1 gun was provided to enable the fuze to be tested. The object of these tests was to demonstrate XM714 delay fuze performance at various impact conditions.

## SECTION II

### TEST PROCEDURES

The test item (Figures 1 and 2) consisted of an XM714 delay fuze and a 20mm high-explosive (HE), thin-walled, lightweight projectile used as a test vehicle. The fuze consisted of the standard XM714 safe and arming (S&A) assembly plus a crush washer, a slide weight and one plastic ball, all enclosed in a solid steel ogive. The nominal weight was 564 grains. The nominal projectile weight was 622 grains and included a plastic rotating band and 193 grains of explosive with a charge-to-mass ratio (C/M) of 0.342.

Three types of tests were conducted:

(1) Structural Integrity - To determine fuze survivability at various impact conditions.

(2) Sensitivity - To determine fuze function against very light material (0.04 inch aluminum), low oblique impact angles (0 degrees) and minimum impact velocities (1500 feet per second).

(3) Function Delay - To determine function delay performance at various impact conditions.

All test projectiles were fired from a 20mm gain twist Mann barrel at a range of 103 feet. Target material was 0.040 to 0.125 inch thick 2024-T3 aluminum. Muzzle velocities were 2500, 3000, and 3500 feet per second and impact angles included 0- to 80-degree obliquities. Target size was 12 x 24 inches (Figure 3) for all structural integrity and function delay tests. A 12 x 12-inch target (Figure 4) was used for the sensitivity test. The target was mounted firmly on all four sides against a 0.75-inch-thick steel plate target frame.

### SECTION III

#### TARGET AND INSTRUMENTATION

Figures 5 and 6 show the range set-up and relative positions of the instrumentation and targets.

Projectile velocity was obtained using circuit paper triggering devices for starting and stopping a counter. The triggering devices were positioned approximately 61 feet and 71 feet downrange from the muzzle (Figure 5).

Two 150-KV x-ray heads were set up along the trajectory (Figure 5). One head was positioned ahead of the target for determining fuze arming and the other head was positioned behind the target for determining delay distance and fuze survivability.

Delay time was recorded by a counter that indicated time between projectile target impact and fuze function. The counter was started by a circuit paper triggering device on the target and stopped by a photo cell that detected projectile detonation flash. Delay time was determined by multiplying the counter time, in  $\mu$ sec, by the projectile velocity.

An aluminum plate (fragment witness plate) positioned behind the target parallel to and lower than the projectile flight path was used as an alternate method of determining fuze delay distance (Figure 7). The fragment pattern on the plate shows a distinct line from which a measurement can be made and used to indicate approximate delay distances.

A secondary target was positioned approximately 5 feet behind the primary target (Figure 5). This target, 0.090 to 0.100 inch aluminum, was used to distinguish between a sensitivity problem and no function. This plate also indicated possible low order detonations.

The witness paper was placed approximately 5 feet behind the secondary target (Figure 5). The witness paper aided in determining a no function or low order detonation.

## SECTION IV

### TEST RESULTS AND DISCUSSION

During this test 266 live rounds and 40 inert rounds, for a total of 306, were fired. Of these, 277 data points were acceptable for evaluation. The remaining 29 were unacceptable due to projectiles hitting the target frame or missing the target completely. The x-ray data and counter time provided an excellent method of determining fuze arming and fuze delay distances. Figure 8 shows a typical x-ray of the projectile before impact. Figure 9 shows an x-ray of a live HE projectile after impact. Figure 10 shows an x-ray of an inert filled projectile after impact. Witness plate measurements are recorded in Table 1. A vector sum of estimated projectile velocity and fragment velocity are not shown due to inconsistent delay distances when using witness plate measurements. The values recorded in Table 1 for the witness plate delay are the measured horizontal and vertical distances from the impact point on the target to the fragment line on the fragment witness plate.

The velocity recorded is an average projectile velocity beginning 61 feet 2 inches downrange and ending 71 feet 2 inches downrange. This velocity is used in computing the delay distance from the x-rays and the counter. The delay distances obtained from the counter are slightly higher than those of the x-rays due to the higher velocity measured uprange from the target. This inaccuracy is acceptable for the purpose of this test.

Table 2 shows the results of the fuze integrity test. The projectile velocities ranged from 2500 to 3500 feet per second. Targets were 0.090 and 0.125 inch thick and positioned at 70- and 80-degree obliquity angles. All projectiles failed at 80 degrees against 0.125 inch targets. Shot number 21 (Figure 16) is representative of a fuze-body interface failure. Shot number 5 (Figure 17) is representative of a fuze body misaligned with respect to the projectile body.

Table 3 shows the results of the fuze sensitivity tests. One of the fuze performance goals is that the fuze will function on 0.040 inch thick 2024-T3 aluminum at 0 degrees impact angle and a projectile velocity of 1,000 feet per second. The shots were made at 1500 feet per second because previous work performed by the contractor indicated that the fuze would not arm at 1,000 feet per second. All five shots failed to function on the primary targets.

Table 1 shows the results of the function delay test. Five data points were collected for each test condition, giving a total of 245 data points. Impact angles varied from 0 to 80 degrees obliquity, target thicknesses ranged from 0.063 inch to 0.125 inch, and nominal projectile velocities varied from 2500 to 3500 feet per second. A total of 60 shots did not function on the primary target; 17 of these did not detonate until hitting the armor plate backstop. Of these 17 shots, only nine were oriented on the x-ray film such that a determination of arming could be

made. Four of the nine indicated no arming. Figures 11 and 12 show a comparison of a properly armed fuze (detonator aligned) and a partially armed fuze (detonator not aligned). Of the 17 shots, 13 were with projectile velocities of 3000 feet per second, and one was with a projectile velocity of 2500 feet per second. Figures 13, 14, and 15 are curves of delay distance versus effective thickness. Effective thickness is the actual thickness that the projectile penetrates. It is determined by dividing the target thickness by the cosine of the oblique angle of impact.

TABLE 1. FUNCTION DELAY (CONCLUDED)

Shot No.	Proj Wt (Gm)	Impact Angle (Deg)	Target Thickness (In)	Proj Velocity (Ft/Sec)	Witness Plate Delay (In)		Counter Delay (Msec)	X-Ray Delay (In)	Remarks
					Vert	Horiz			
241	80.1	80	0.125	3526	2.0	2.0	58	2.5	*
242	79.8			3536	2.0	3.0	69	2.9	*
243	80.4			3511	2.5	3.5	*	*	*
244	80.1			3441	2.0	2.0	76	3.1	*
245	79.9	80	0.125	3446	*	*	83	3.4	*

For Shot Numbers 86 and 88:

- > The detonation time could not be accurately determined because the x-ray captured the projectile image a long time after projectile detonation. Therefore, a conservative estimate was used providing for a computed x-ray delay distance lower than expected.

TABLE 2. FUZE INTEGRITY
